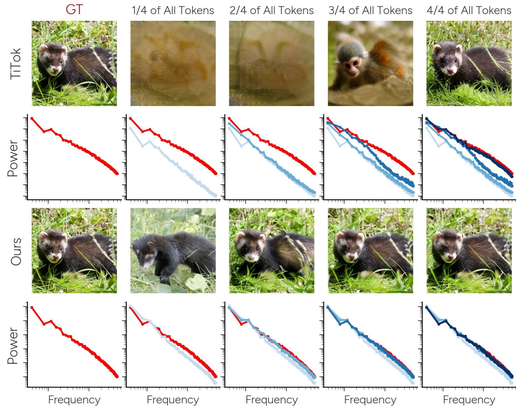
What makes this tokenizer different?

- **1D Causal Tokenization** – An ordered structure where token importance follows a hierarchical pattern.
- **PCA-Like Structure** – Earlier tokens contain most significant information, while later tokens refine details.
- **Semantic-Spectrum Decoupling** – ensuring tokens capture high-level rather than low-level artifacts.

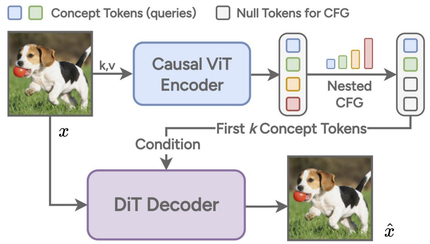
1. Semantic-Spectrum Decoupling



TiTok: both semantic details and spectral power increase simultaneously.

Ours:

1) **Semantic clarity w/ few tokens.**
2) **Consistent spectrum across token counts.**
3) **Coarse-to-fine hierarchy, mirroring global precedence effect in human vision.**



2. Semanticist

1) **Causal ViT Encoder**
2) **Nested Dropout for PCA-like Structure**
3) **Diffusion-Based DiT Decoder**

3. Reconstruction with A Variable Number of Tokens

Method	#Token	Dim.	VQ	rFID↓	PSNR↑	SSIM↑	Gen. Model	Type	#Token	#Step	gFID↓	IS↑
MaskBit [55]	256	12	✓	1.61	–	–	MaskBit	Mask.	256	256	1.52	328.6

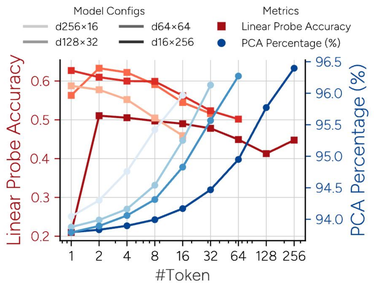
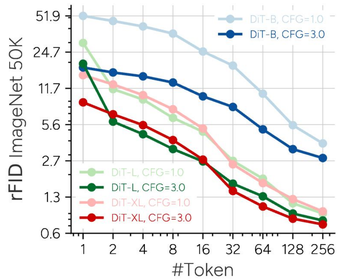
Competitive understanding, reconstruction, and AR generation.
Top: quantitative results on ImageNet reconstruction and autoregressive generation.
Left: linear probing; Right: reconstruction FID.

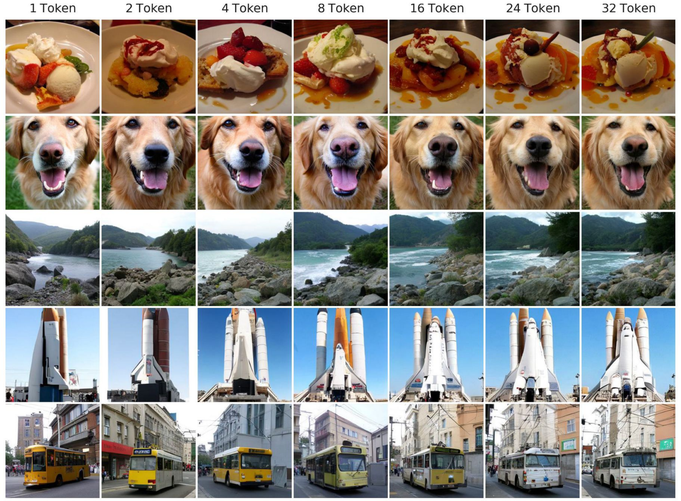




4. AR Generation with A Variable Number of Tokens (w/ LlamaGen)

Code & Models

Project Page



5. Discussion

Potential Applications

- Unified understanding & generation, image compression, data analysis, etc.

Limitations/Future Work

- **Inference Speed:** Diffusion decoding is slower than direct pixel regression.
- **Alternative Architectures:** Flow-matching or consistency models could improve efficiency.
- **Random Ordering:** Compatible to random-ordered tokens could be useful.
